

Assignment - 3 Report

Submitted By: Kshitij Srivastava (MT18099)

Question 1: Segmentation using K-means clustering

Part A: Using 3-dimensional color space

Original

K = 2

Original

K = 4

Original

K = 7

Original

K = 6

Part B: Using 5-dimensional space

Original

$K = 4$

Original

$K = 10$

Original

$K = 10$

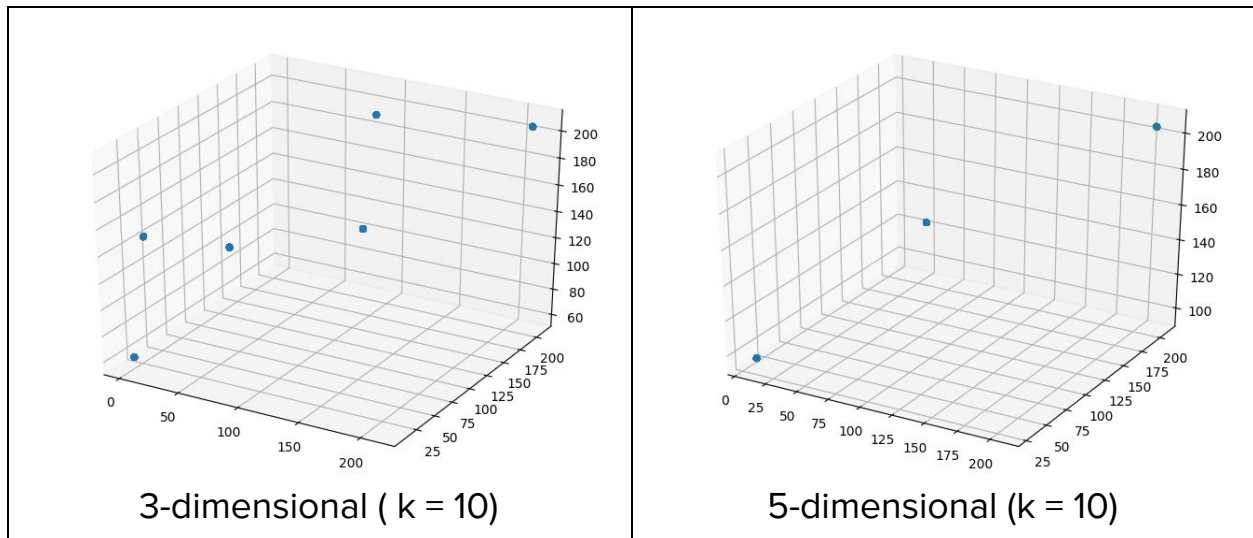

Original

$K = 6$

Scatter Plots:

Observations:

- From the cluster plots, we can see that using 3-dimensional color space gives better results than using 5-dimensional space.
- This is probably because of the fact that in 5-dimensional space, the spatial property of a pixel also plays a major role in deciding the centroid of the cluster and hence, pixels of different colors are also clustered together.
- The scatter plot provides more evidence to the above statement, we can see that there are clearly more cluster points in the 3-dimensional color space in comparison to the 5-dimensional color space.

Question 2: Mean-shift clustering

Original

quantile=.04, n_samples=1000

Original

quantile=.04, n_samples=1000

Original

quantile=.04, n_samples=1000

Choice of parameters:

- I chose the above parameters based on trial and error.
- However, I did observe that the smaller the value of quantile was, the greater was the number of clusters formed.
- And the lower the value of n_samples, the lower the number of clusters formed.

Question 3:

Part A: Skin Color Thresholding

- I have used a mixture of RGB, YCbCr and HSV color space thresholds for this.
- Images have been binarized.
- Ref: https://github.com/WillBrennan/SkinDetector/tree/master/skin_detector

Part C: Seeded Segmentation
